High-Performance Computing

Parallel Programming in OpenMP – part II

Outline

- □ Data scoping cont'd
- Orphaning
- Tasking
- OpenMP correctness & Data Races
- Runtime library
- Scheduling
- □ A real world example

Programming OpenMP

More on data scoping

02614 - High-Performance Computing

3

OpenMP Syntax

Reminder: the "private" clause -

declares variables private to each thread:

#pragma omp directive private (list)

- □ i.e. a **new** variable is declared once for each thread
- all references are replaced with references to the newly declared variable
- variables declared private are uninitialized for each thread!

Consequences of private(...):

January 2021

02614 - High-Performance Computing

5

OpenMP Syntax

Solutions:

```
#pragma omp ... firstprivate(list)
```

All variables in list are initialized with the value the original object had before entering the parallel construct.

```
#pragma omp ... lastprivate(list)
```

☐ The thread that executes the <u>sequentially</u> <u>last</u> iteration updates all variables in list.

The "threadprivate" and "copyin" clauses:

- threadprivate(list): creates a private copy of global data (e.g. common blocks or global variables in modules in Fortran) for each thread
- copyin(list): copies the values from the master thread into the private copies – like a 'firstprivate' for global variables
- subsequent modificications of list affect only the private copies – within one parallel region

January 2021

02614 - High-Performance Computing

7

OpenMP Syntax

Example 1:

```
int counter = 0;
#pragma omp threadprivate(counter)

int increment_counter()
{
    counter++;
    return(counter);
}

INTEGER FUNCTION INCREMENT_COUNTER()
    COMMON/A22_COMMON/COUNTER
!$OMP THREADPRIVATE(/A22_COMMON/)
    COUNTER = COUNTER +1
    INCREMENT_COUNTER = COUNTER
    RETURN
END FUNCTION INCREMENT COUNTER
```

Example 2:

```
int
increment_counter()
{
    static int counter = 0;
    #pragma omp threadprivate(counter)

    counter++;
    return(counter);
}
```

02614 - High-Performance Computing

9

OpenMP Syntax

The copyprivate(...) clause

copying a value out of a single region into the private data of other threads

```
#pragma omp single copyprivate(list)
{
    ...
}
!$OMP SINGLE ....
!$OMP END SINGLE COPYPRIVATE(LIST)
```

Example:

January 2021

02614 - High-Performance Computing

14

OpenMP Syntax

Example (cont'd):

Example output:

```
$ OMP NUM THREADS=3 ./copypriv
1 2 3 4
            TID 2: a = 1, b = 2, c = 3, d = 4
            TID 1: a = 1, b = 2, c = 3, d = 4
            TID 0: a = 1, b = 2, c = 3, d = 4
In main - TID 0: a = 1, b = 2, x = 3, y =
In main - TID 1: a = 1, b = 2, x = 3, y = 4
In main - TID 2: a env OMP NUM_THREADS=3 ./copypriv
                                TID 1: a = 0, b = 1, c = 3, d = 4
                                TID 0: a = 0, b = 0, c = 3, d = 4
                               TID 2: a = 1, b = 2, c = 3, d = 4
                       In main - TID 2: a = 1, b = 2, x = 3, y = 4
without copyprivate
                       In main - TID 0: a = 0, b = 0, x = 3, y = 4
                       In main - TID 1: a = 0, b = 1, x = 3, y = 4
  on r a and r b
```

02614 - High-Performance Computing

OpenMP Orphaning

Orphaning in OpenMP

January 2021

16

OpenMP Orphaning

The OpenMP standard does not restrict worksharing and synchronization directives to be within the lexical extent of a parallel region. Those directives can be orphaned, i.e. they can appear outside a parallel region:

```
void dowork(void) {

#pragma omp parallel

#pragma omp for
for(i=0; i<N; i++) {

corphaned
worksharing
directive</pre>
```

January 2021

02614 - High-Performance Computing

18

OpenMP Orphaning

- When an orphaned directive is detected within the dynamic extent of a parallel region, its behaviour is similar to the non-orphaned case.
- When an orphaned directive is detected in the sequential part of the program, it will be ignored.

```
dowork(); // serial for

#pragma omp parallel
{
    :
    dowork(); // parallel for
    :
}
```

```
void dowork(void) {
    :
    #pragma omp for
    for(i=0; i<N; i++) {
    }
    :
}</pre>
```

Tasking (since OpenMP 3.0)

- allows parallelization of work that is generated dynamically
- provides a flexible model for irregular parallelism
- □ uses a "task pool" concept
- new opportunities:
 - while loops
 - recursive structures

January 2021

02614 - High-Performance Computing

21

OpenMP syntax

□ Syntax C/C++:

```
#pragma omp task [clause]
{
    ...
}
```

- clause can be
 - if (int_expr)
 - default(shared|none)
 - private(list), shared(list)
 - firstprivate(list)
 - untied

Syntax Fortran:

```
!$OMP task [clause]
...
!$OMP end task
```

- where clause can be
 - if (int_expr)
 - default(shared|private|firstprivate|none)
 - private(list), shared(list)
 - firstprivate(list)
 - untied

January 2021

02614 - High-Performance Computing

23

OpenMP syntax

Tasking example I:

while loop:

parallel while loop with OpenMP tasks:

```
p = lhead;
while (p != NULL)
{
   do_work(p);
   p = next(p);
}
```

02614 - High-Performance Computing

What's going on?

```
-start of parallel region
#pragma omp parallel
  #pragma omp single
                                      one thread only, please
     p = lhead;
     while (p != NULL) {
        #pragma omp task
                                       task generation – tasks
                                       are added to the task
         do work(p);
                                       list
                                      all work is done here!
        p = next(p);
                                       implicit barrier - all
  } // end of single
                                       unfinished tasks have
                                       to be finished
    // end of parallel
```

January 2021

02614 - High-Performance Computing

25

OpenMP syntax

- Tasks and recursion: calculating Fibonacci numbers
- □ Recursive scheme to calculate the nth Fibonacci number:

 - □ stopping critererion: return 1 if n < 2
- Caveat: this method is not very effective, but used here to demonstrate the concept of tasking!

The sequential code:

```
int
main(int argc, char* argv[]) {
    [...]
    fib(input);
    [...]
}

int
fib(int n) {
    int x, y;
    if (n < 2) return n;
    x = fib(n - 1);
    y = fib(n - 2);
    return(x + y);
}</pre>
```

02614 - High-Performance Computing

27

OpenMP syntax

OpenMP version of fib() with tasks:

```
int
fib(int n) {
   int x, y;
                                         note the special
   if (n < 2) return n;
                                          scoping rules!
   #pragma omp task shared(x)
   x = fib(n - 1);
                                        generate two tasks,
   #pragma omp task shared(y)
                                       calling fib() recursively
   y = fib(n - 2);
                                       task synchronization -
   #pragma omp taskwait
                                       to get the right results
   return(x + y);
```

Scoping rules with tasks:

- Static and global variables are shared
- Local (aka automatic) variables are private
- Orphaned task variables are firstprivate
- Non-orphaned task variables inherit the shared attribute
- (Local) Task variables are firstprivate, unless declared shared
- ☐ Thus, we have to declare x and y as shared

January 2021

02614 - High-Performance Computing

29

OpenMP syntax

Task synchronization:

- □ #pragma omp taskwait
- suspends the encountering task, until all child tasks are completed
- direct children only, not descendants
- needed here, to make sure that x and y are still exist when we take the sum.

OpenMP version of main() with tasks:

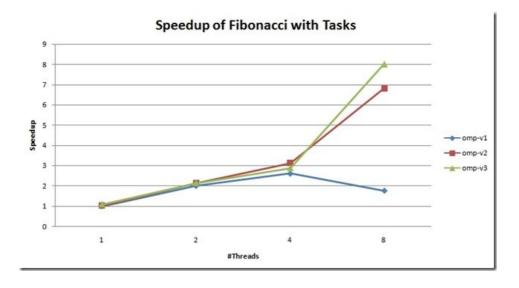

January 2021

02614 - High-Performance Computing

31

OpenMP syntax

Results of the Fibonacci program

courtesy: Chr. Terboven, RWTH Aachen

Notes on the Fibonacci speedup results:

- □ The simple OpenMP version (omp-v1) doesn't scale – as expected – due to the large amount of tasks generated
- □ Improvement 1 (omp-v2):
 - add an if-clause to the tasks: #pragma omp task if(n>=30) shared(...)
 - improves the speed-up, but still not perfect
- □ Improvement 2 (omp-v3): (see next slide)

January 2021

02614 - High-Performance Computing

33

OpenMP syntax

version omp-v3 of fib() with tasks:

```
int
fib(int n) {
   int x, y;
   if (n < 2) return n;
   if (n < 30) {
      return(fib(n-1) + fib(n-2));
   }
   #pragma omp task shared(x)
   x = fib(n - 1);
   #pragma omp task shared(y)
   y = fib(n - 2);
   #pragma omp taskwait
   return(x + y);
}</pre>
```

Some notes on tasking:

- tasks allow to exploit parallelism with OpenMP, that hasn't been possible before
- the tasking concept has the main focus for future versions of OpenMP, and has been extended in versions 4.x and 5
- this goes beyond our scope in this course

January 2021

02614 - High-Performance Computing

35

OpenMP: Error detection

Tools to check your OpenMP code

OpenMP compile-time checks

OpenMP checks supported by Oracle Studio compilers:

- -xloopinfo info on loops
- -xvpara compile time warnings on ...
 - ... scoping problems
 - ... possible data races

January 2021

02614 - High-Performance Computing

37

OpenMP run-time checks

OpenMP run-time checks supported by Oracle Studio:

- SUNW_MP_WARN = [true|false]
 - gives you warnings at runtime
 - e.g. dynamic change of threads
 - inconsistencies of barriers
 - □ ...
- □ Note: there is a certain performance penalty

OpenMP run-time checks

Example: illegal usage of a barrier

```
1 #include <omp.h>
 2 #include <stdio.h>
 4 int main (void)
     #pragma omp parallel num threads(4)
 8
         int i = omp get thread num();
 9
10
         if (i % 2) {
              printf("At barrier 1.\n");
11
12
              #pragma omp barrier
13
         }
14
15
     return 0;
16 }
```

January 2021

02614 - High-Performance Computing

39

OpenMP run-time checks

Example (cont'd): illegal usage of a barrier

```
$ suncc -g -x03 -xopenmp -xvpara -o bad1 bad1.c
$ ./bad1
                               no compiler warning!!
At barrier 1.
At barrier 1.
^C
$ SUNW MP WARN=true ./bad1
WARNING (libmtsk): Environment variable SUNW MP WARN is set
    to TRUE. Runtime error checking will be enabled.
At barrier 1.
At barrier 1.
WARNING (libmtsk): Threads at barrier from different directives.
    Thread at barrier from bad1.c:6.
    Thread at barrier from bad1.c:12.
    Possible Reasons:
    Worksharing constructs not encountered by all threads in
    the team in the same order.
    Incorrect placement of barrier directives.
WARNING (libmtsk): Runtime shutting down while some parallel
    region is still active.
```

Oracle Studio has a data race detection tool:

- □ Thread Analyzer (tha)
- Quick usage guide:
 - □ compile and link with -xinstrument=datarace
 - □ run it: collect -r on a.out
 - □ view results (GUI): tha tha.1.er
 - □ or CLI: er_print -races tha.1.er

January 2021

02614 - High-Performance Computing

41

OpenMP: Data Race Detection

Example:

```
int main(int argc, char *argv[]) {
    int i, total = 0, N = 20000000;
    int primes[N];
    #pragma omp parallel for
    for( i = 2; i < N; i++ ) {
        if ( is_prime(i) ) {
            primes[total] = i;
            total++;
        }
    }
    printf("# of prime numbers between 2 and %d: %d\n",
            N, total);
    return(0);
}</pre>
```

Example (cont'd): compile and run

```
$ suncc -q -fast -o prime prime.c
$ ptime ./prime
# of prime numbers between 2 and 2000000: 148933
           10.862
real
user
           10.483
            0.056
sys
$ suncc -q -fast -xopenmp -xloopinfo -o prime prime.c
$ "prime.c", line 7: PARALLELIZED, user pragma used
$ OMP NUM THREADS=4 ptime ./prime
# of prime numbers between 2 and 2000000: 148310
            3.662
                    <--- speed-up: 2.9x
real
           10.494
user
            0.055
sys
```

January 2021

02614 - High-Performance Computing

43

OpenMP: Data Race Detection

Example (cont'd): run, run, ... and use collect

```
$ OMP_NUM_THREADS=4 ./prime
# of prime numbers between 2 and 2000000: 148310

$ OMP_NUM_THREADS=4 ./prime
# of prime numbers between 2 and 2000000: 148328

$ suncc -g -fast -xopenmp -xinstrument=datarace \
    -o prime prime.c

$ OMP_NUM_THREADS=4 collect -r on ./prime
Creating experiment database tha.1.er ...
# of prime numbers between 2 and 2000000: 125581
$
```

Example (cont'd): analyze the collect data

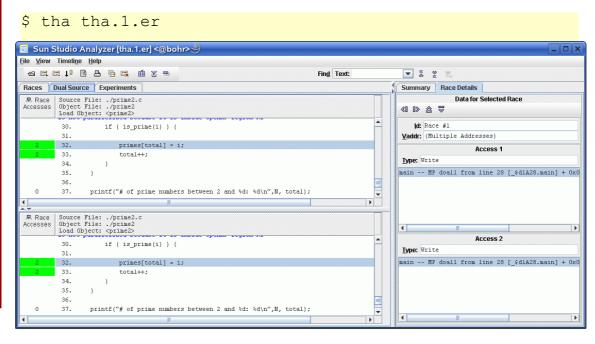

January 2021

02614 - High-Performance Computing

45

OpenMP: Data Race Detection

Example (cont'd): analyze the collect data

Example (cont'd): fix the bug

```
int main(int argc, char *argv[]) {
     int i, total = 0, N = 2000000;
     int primes[N];
     #pragma omp parallel for
     for (i = 2; i < N; i++) {
          if ( is prime(i) ) {
              #pragma omp critical
              { primes[total] = i;
                total++;
          }
     printf("# of prime numbers between 2 and %d: %d\n",
             N, total);
     return(0);
January 2021
                     02614 - High-Performance Computing
                                                               47
```

OpenMP: Data Race Detection

Example (cont'd): check – and recompile

```
$ suncc -g -fast -xopenmp -xinstrument=datarace \
  -o prime prime.c
$ OMP NUM THREADS=4 collect -r on ./prime
Creating experiment database tha. 2.er ...
# of prime numbers between 2 and 2000000: 148933
$ er print -races tha.2.er
Total Races: 0 Experiment: tha.2.er
$ cc -q -fast -xopenmp -o prime prime.c
$ OMP NUM THREADS=4 ptime ./prime
# of prime numbers between 2 and 2000000: 148933
            3.561
real
           10.393
user
            0.051
sys
```

- Some notes:
 - Oracle Studio does only support OpenMP up to version 4.0
 - most of the features we use here are supported, but not all
 - thus, using this tool will not work for everything

January 2021

02614 - High-Performance Computing

49

OpenMP Scheduling

Controlling the scheduling of OpenMP threads

Load balancing:

- Important aspect of performance
- Especially for less regular workloads, e.g.
 - transposing a matrix
 - multiplications of triangular matrices
 - parallel searches in a linked list
- □ The schedule clause provides different iteration scheduling algorithms for loops

January 2021

02614 - High-Performance Computing

51

OpenMP Scheduling

The "schedule" clause:

```
#pragma omp for schedule(static[,chunk])
#pragma omp for schedule(dynamic[,chunk])
#pragma omp for schedule(guided[,chunk])
#pragma omp for schedule(auto) - new in 3.0
#pragma omp for schedule(runtime)
```

□ If there is no schedule clause, the default is static.

#pragma omp for schedule(static[,chunk])

Static schedule:

- □ Iterations are divided into pieces of size chunk and then **statically** assigned to the threads.
- ☐ If chunk is not defined, the work (N) is equally divided among the number of threads (P), i.e. chunk = N/P.

January 2021

02614 - High-Performance Computing

53

OpenMP Scheduling

#pragma omp for schedule(dynamic[,chunk])

Dynamic schedule:

- □ Iterations are divided into pieces of size chunk and then **dynamically** assigned to the threads i.e. when a thread has finished one chunk, it is assigned a new one.
- ☐ The default chunk size is 1.

#pragma omp for schedule(guided[,chunk])

Guided schedule:

□ The chunk size is exponentially reduced with each chunk that gets dynamically assigned to the threads; chunk defines the minimum number of iterations to assign each time.

chunk = unass_iter/(weight * n_thr)

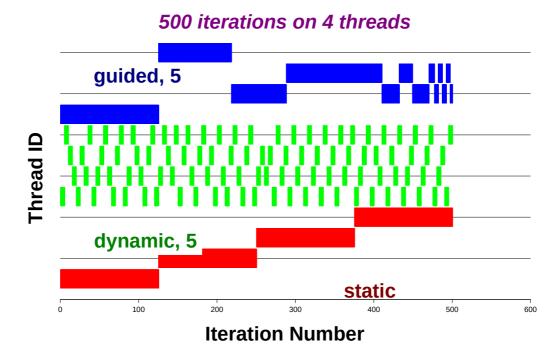

□ The default minimum chunk size is 1.

02614 - High-Performance Computing

55

OpenMP Scheduling

#pragma omp for schedule(runtime)

Runtime schedule:

- □ The schedule is detected at runtime from the setting of the OMP_SCHEDULE environment variable.
- Syntax: OMP_SCHEDULE=type,chunk

January 2021

02614 - High-Performance Computing

57

OpenMP Scheduling

#pragma omp for schedule(auto)

Automatic schedule (new in OpenMP 3.0):

■ When schedule(auto) is specified, the decision regarding scheduling is delegated to the compiler and/or runtime system. The programmer gives the implementation the freedom to choose any possible mapping of iterations to threads in the team.

A real world example: Molecular Dynamics simulation

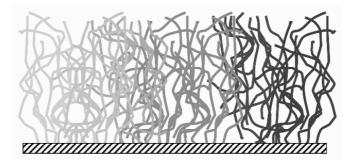

02614 - High-Performance Computing

59

Example: MD simulation

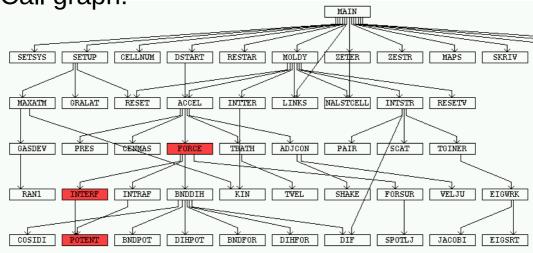

Molecular Dynamics simulation of long carbon molecules on a surface:

- □ 7200+ lines of Fortran 77 code
- □ GOTOs, COMMON blocks, ...
- one source file

Call graph:

more than 80% of the runtime are spent in the red part of the call graph

January 2021

02614 - High-Performance Computing

61

Example: MD simulation

- ☐ The loop to be parallelized contains a call to another subroutine.
- Data is passed the old Fortran style via COMMON blocks
- First try: Inserted one PARALLEL DO pragma in the code, using autoscoping, i.e. a feature of the Oracle Studio compiler
- ☐ The compiler generated a parallel version!

This took us by surprise!

- First test runs:
 - It didn't scale ...
 - ☐ The results were dependent on the number of threads ...
- Thread analyzer revealed data races in two variables inside the called subroutine.
- □ Fix: Added additional scoping for those variables in the OpenMP pragma!
- This solved the data race problem.

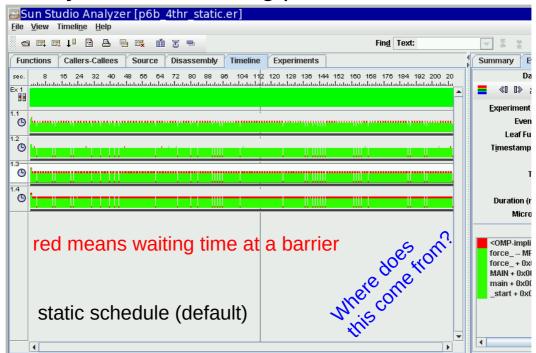

January 2021
